INSTRUCTIONS FOR PREPARING LAB REPORT

Prepare your lab record in the usual format with the following headers:

Aim: Quantitative methods in Biology: Measuring the relationship between plant height, and stem girth

Materials: string or measuring tape, scale

Theory: This should provide a short description on the theory we discussed in the class, about hypotheses, null and alternate, variable measurements, study design etc.

The lab exercise is an example of the application of this theory. Select any species of shrub (avoid a tree) on our campus. **If possible, take a picture of the plant you selected, and take a printout of this and stick it on your record**, so that the species you have selected can be identified.

Results: this must contain the details of the data you collected as per the instructions in the class (slides of this are provided on WeLearn). Make proper tables (showing your data on the individual tree height and girth measurement, the overall mean and standard deviation) and required graphs (bar graphs showing mean plant height and girth, and scatterplot graph to show relationship between plant height and girth) to show your results.

Conclusions: What have you found about the relationship between the plant height, and stem girth? Do they seem to agree with your null or alternate hypotheses? Why?

Names of students group who did the data collection part- give all names of your class mates with whom you conducted your study.
